### **THEORY**

In our cloth simulation, we follow the precedure written by Rohmer et al.. We consider to begin with the  $Defomation\ gradient\ \mathbf{F}$ , which is defined by

$$\mathbf{F} = \frac{\partial \mathbf{x}}{\partial \mathbf{X}},\tag{1}$$

where the  ${\bf x}$  denotes the deformed vector and the  ${\bf X}$  denotes the reference vector.

Since we have no further information about the mapping from  ${\bf X}$  to  ${\bf x}$ , we use the vector  $({\bf u_1},{\bf u_2})$  and  $(\overline{{\bf u_1}},\overline{{\bf u_2}})$  to approximate the Defomation gradient, which is defined as

$$\mathbf{F} = \left[\mathbf{u}_{1}, \mathbf{u}_{2}\right] \left[\overline{\mathbf{u}_{1}}, \overline{\mathbf{u}_{2}}\right]^{-1},\tag{2}$$

Attention should be paid especially:

- eq.(2) characrize only the 2D deformation of each triangle.
- in Rohmer et al. **F** is symbolised as **T**.

We provide here our code preceed with concrete data:

• faces(i,j) is the jth vertex of the ith triangle, here we choose the face(0,0), face(0,1), face(0,2) as examples and calculate the VecT and VecR for face(0,0).

#### cloth\_vec

$$VecT = el_1 VertT_1 - el_1 VertT_2$$
;  $el_1 VertT_1 - el_1 VertT_3$  (3)

$$VecR = el_1 VertR_1 - el_1 VertR_2$$
;  $el_1 VertR_1 - el_1 VertR_3$  (4)

#### cloth\_vec

$$VecT = [0.771842 - 0.0144887 \ 6.39045] - [0.780121 - 0.0186188 \ 6.37318]$$
 (5)

$$[0.771842 - 0.0144887 \ 6.39045] - [0.737177 - 0.00912791 \ 6.39292]$$

$$VecR = [0.759919 - 0.015194 \ 6.38401] - [0.767822 - 0.0212492 \ 6.3669];$$
 (7)

$$[0.7599190.015194 \ 6.38401] - [0.726977 \ -0.00749985 \ 6.38692]$$

#### such that

### cloth\_vec

$$VecT = [-0.0079 \ 0.0061 \ 0.0171 \ 0.0329 \ -0.0077 \ -0.0029];$$
 (10)

$$VecR = [-0.0083 \ 0.0041 \ 0.0173 \ 0.0347 \ -0.0054 \ -0.0025];$$
 (11)

(12)

where the first 3 entries of VecR is the vector  $\mathbf{u_1}$  and the last 3 entries of VecR is the vector  $\mathbf{u_2}$ . VecT analogiously.

### cloth\_eig\_2D

we use here Eigen :: Map to transform the vector VecT and VecR to 2 \* 2 2D deformation gradient  $\mathbf{F}$ .

$$\mathbf{F} = \begin{bmatrix} -0.0083 & 0.0347 \\ 0.0041 & -0.0054 \end{bmatrix} \begin{bmatrix} -0.0079 & 0.0329 \\ 0.0061 & -0.0077 \end{bmatrix}^{-1}$$
 (13)

Sikang Yan (TUK) Short title March 2, 2019 6/19

hence the F has a rotation information R and a stretch information U,

$$F = RU. (14)$$

we use  $\mathbf{F}^T\mathbf{F}$  to eliminate the ratotion information to obtain det  $\mathbf{R}=1$ 

$$\mathbf{F}^{T}\mathbf{F} = (\mathbf{R}\mathbf{U})^{T}\mathbf{R}\mathbf{U} \tag{15}$$

$$=\mathbf{U}^{T}\mathbf{R}^{T}\mathbf{R}\mathbf{U} \tag{16}$$

$$=\mathbf{U}^2\tag{17}$$

$$=\mathbf{C} \tag{18}$$

and using decomposition, if we have the form

$$\mathbf{C} = \lambda_1^2 \mathbf{v}_1 \mathbf{v}_1^T + \lambda_2^2 \mathbf{v}_2 \mathbf{v}_2^T \tag{19}$$

then we could obtain the **U** by applying

$$\mathbf{U} = \lambda_1 \mathbf{v}_1 \mathbf{v}_1^T + \lambda_2 \mathbf{v}_2 \mathbf{v}_2^T \tag{20}$$

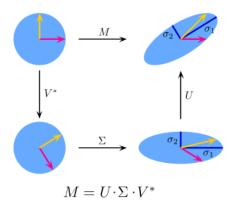

Figure: Singular Value Decomposition SVD

the main backdraw of Rohmer et al. is that this is only applied for 2D problem, thus we need a new algorithm, which can also take the consideration for the vertical deformation. Therefore, the *Kabisch Algorithm* is introduced.

#### Kabisch Algorithm

Let  ${\bf P}$  denotes the points set of template frame, and  ${\bf Q}$  denotes the points set of reference frame. The *optimal rotation matrix*  ${\bf R}$  can be calculted as

$$\mathbf{R} = \mathbf{V} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & d \end{bmatrix} \mathbf{U}^{T}$$
 (21)

where  $\mathbf{V}$  and  $\mathbf{U}$  and the SVD of cross-covariance matrix  $\mathbf{H}$ , which is determined by

### Theorem (cross-covariance matrix)

$$\mathbf{H} = \mathbf{P}^{T} \mathbf{Q} \tag{22}$$

and  $d = \det \mathbf{V} \mathbf{U}^T$ 

9 / 19

The matrix  ${\bf H}$  is derived from the *orthogonal Procrustes problem*[?]. It is defined as the least-squares problem of transforming a given matrix  ${\bf P}$  into a given matrix  ${\bf Q}$  by an orthogonal transformation matrix  ${\bf R}$ , such that the sums of squares of the residual matrix  ${\bf E}=\Omega{\bf P}-{\bf Q}$  is a minimum

$$\mathbf{R} = \underset{\Omega}{\text{arg min}} \|\mathbf{\Omega}\mathbf{P} - \mathbf{Q}\|_{F} \quad \text{subject to} \quad \mathbf{\Omega}^{T}\mathbf{\Omega} = \mathbf{I}, \tag{23}$$

where  $\|\cdot\|_F$  is the Frobenius norm. This problem is equivalent to find the nearest orthogonal matrix  $\mathbf{R}$  to a given matrix  $\mathbf{H} = \mathbf{P}^T \mathbf{Q}$  [?], which most closely maps  $\mathbf{P}$  to  $\mathbf{Q}$ . Thus, we use  $\mathbf{H}$  to approximate the deformation gradient  $\mathbf{F}$  in Eq. (??)

$$\widetilde{\mathbf{F}} = \mathbf{H}.$$
 (24)

The cross-covariance matrix discribe the covariance of one process with the other at pairs of time points and measure of similarity. We use therefore the cross-covariance matrix  ${\bf H}$  to approximate our deformation gradient  ${\bf F}$ .

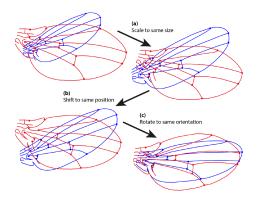

Figure: Procrustes superimposition

Sikang Yan (TUK) Short title March 2, 2019 11/19

Let i be the all index set of the nearst vertice of vertex I in the template frame and  $\bar{i}$  be the all index set of the nearst vertice of vertex I in the template frame. Process define

$$\mathbf{P} = \begin{bmatrix} \vec{x}_1 \ \vec{y}_1 \ \vec{z}_1 \\ \vec{x}_2 \ \vec{y}_2 \ \vec{z}_2 \\ \vdots \\ \vec{x}_N \ \vec{y}_N \ \vec{z}_N \end{bmatrix} \quad 1, 2, \dots, N \in i$$
 (25)

$$\mathbf{Q} = \begin{bmatrix} \overline{\vec{x}}_1 & \overline{\vec{y}}_1 & \overline{\vec{z}}_1 \\ \overline{\vec{x}}_2 & \overline{\vec{y}}_2 & \overline{\vec{z}}_2 \\ \vdots & \vdots & \end{bmatrix} \quad 1, 2, \dots, N \in \overline{i}$$

$$(26)$$

and we apply to obtain the deformation gradient  $\mathbf{F}$  of vertex I

$$\mathbf{F} = \mathbf{P}^{T} \mathbf{Q} \tag{27}$$

Sikang Yan (TUK) Short title March 2, 2019 12/19

Whereas the deformation gradient measures the local deformation, the spacial velocity gradient L describes the rate of deformation, given by

$$\mathbf{L} = grad\mathbf{v} = \dot{\mathbf{F}}\mathbf{F}^{-1},\tag{28}$$

where  $\mathbf{v}$  denotes the *velocity* of the material point  $\mathbf{X}$ , and  $\mathbf{F}$  denotes the material time derivative of deformation gradient **F**.

Analogically, we apply the polar decomposition on the spacial velocity gradient L[?], and obtain

$$\mathbf{L} = \mathbf{D} + \mathbf{W}. \tag{29}$$

Thus, we could decompose the tensor L into its symmetric part D and skew-symmetric part W

$$\mathbf{D} = \frac{1}{2} (\mathbf{L} + \mathbf{L}^T), \tag{30}$$

$$\mathbf{W} = \frac{1}{2} (\mathbf{L} - \mathbf{L}^T). \tag{31}$$

$$\mathbf{W} = \frac{1}{2} (\mathbf{L} - \mathbf{L}^T). \tag{31}$$

where **D** is called the *rate of strain tensor* and **W** is called the *rate of* rotation tensor.

Assuming  $d\mathbf{x}$  is a material line element in the current configuration, the rate of change of its length  $\dot{\epsilon}_{ii}$  and angle  $\dot{\gamma}_{ij}$  is measured by means of **D**[?].

$$\dot{\epsilon}_{ii} = \mathbf{e}_i \mathbf{D} \mathbf{e}_i = D_{ii} \tag{32}$$

$$\dot{\gamma}_{ij} = 2\mathbf{e}_i \mathbf{D} \mathbf{e}_j = D_{ij} \tag{33}$$

where  $D_{ii}$  are the ij-entries of **D**. Additionally, if **D** has the same base  $\mathbf{e_1}, \mathbf{e_2}, \mathbf{e_3}$  as in eq.(20), than

$$D_{11} = \frac{\dot{\lambda}_1}{\lambda_1}$$

$$D_{22} = \frac{\dot{\lambda}_2}{\lambda_3}$$

$$D_{33} = \frac{\dot{\lambda}_2}{\lambda_3}$$

$$(34)$$

$$(35)$$

$$D_{22} = \frac{\dot{\lambda}_2}{\lambda_3} \tag{35}$$

$$D_{33} = \frac{\dot{\lambda}_2}{\lambda_3} \tag{36}$$
